The cache is not meant for reliable transfer, it's meant to avoid duplicate work on a best-effort basis. So I'd advise against this approach even if it happened to be working right now. 😅

What you should do instead is to use artifacts, see Storing workflow data as artifacts - GitHub Docs. Artifacts are meant exactly for the kind of scenario you describe, where data needs to be passed between parts of a build (or out of it).

If your artifacts are large and you don't want to keep using the storage, you can set a short retention period when uploading the artifact.
